

THE APPLE-SNAILS OF SIAM.

ADDENDUM.

Pachylabra winkleyi (Pilsbry).

1901. *Ampullaria Winkleyi*, Pilsbry, *Proc. Ac. Nat. Sci. Philadelphia*, LIII, p. 189, pl.V, figs. 2, 3.

Since I corrected the proofs of this paper I have discovered an interesting specimen from my own Tale Sap collection that had been temporarily mislaid. It agrees very closely, except in being considerably smaller, with Pilsbry's figure of this species, differing from *L. begini* in the well-marked flatness of the whorls outside the suture and in the very fine, minutely granular transverse striae. The external surface is pale olivaceous with occasional, irregular black longitudinal streaks. The inside of the lip is yellowish but the margin white.

It is evident that I was wrong in identifying the form common in the Southern Shan States (*Rec. Ind. Mus.*, XIV, p. 138; 1918) with *P. winkleyi*. It can hardly be distinguished from *P. maura* (Reeve), which is certainly not more than an eastern local race of *P. globosa* (Swainson), the species common in the Ganges valley.

P. winkleyi was originally described from Henzada in Pegu and has not hitherto been recorded from Siam.

N. ANNANDALE.
